

Verifying the Product of Generalized Boolean Matrix Multiplication and Its Applications to Detect Small Subgraphs

Wing-Kai Hon, **Meng-Tsung Tsai**, and Hung-Lung Wang

WADS 2023

NTHU, Taiwan

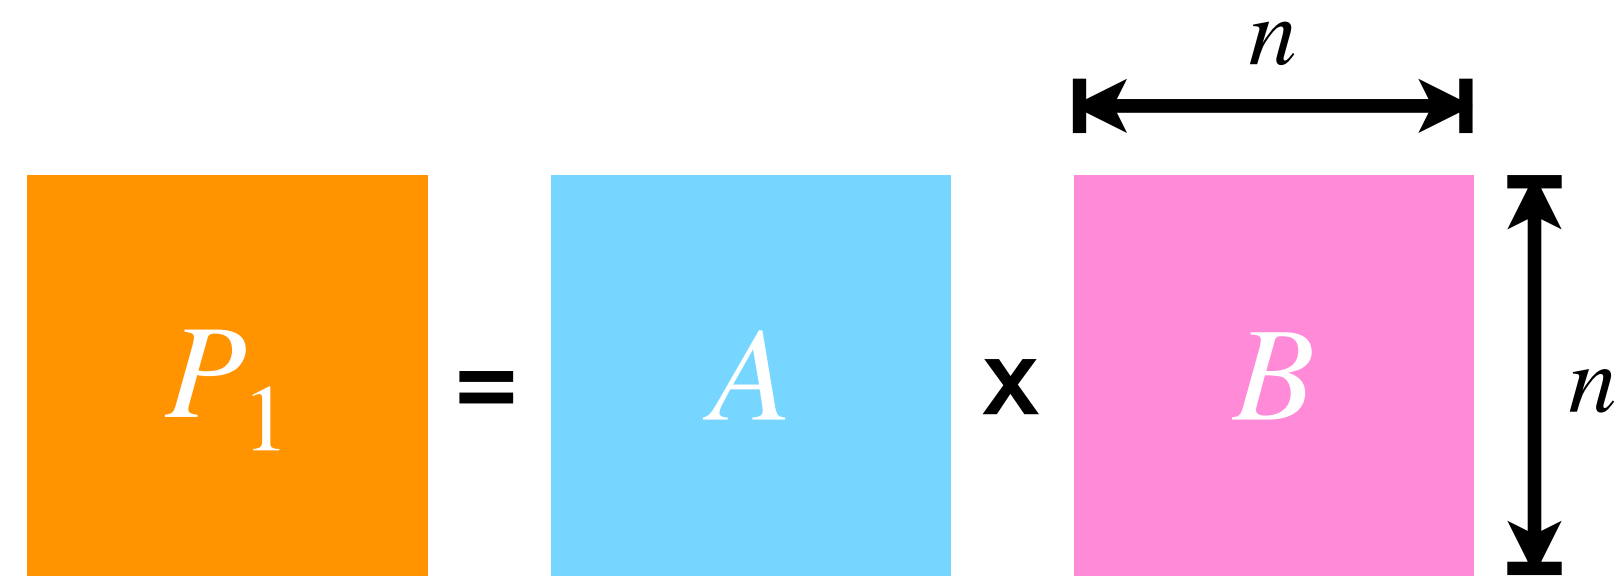

Academia Sinica, Taiwan

NTNU, Taiwan

Problem Definition

$$P_1 = A \times B$$

$$P_2 = A \times \bar{B}$$

$$P_3 = \bar{A} \times B$$

$$P_4 = \bar{A} \times \bar{B}$$

Input:

(1) two n by n Boolean matrices A and B

(2) a non-empty subset S of $\{P_1, P_2, P_3, P_4\}$ (given as symbols rather than the explicit matrices)

Output:

“Yes”, if the entry-wise logical-and of all matrices in S contains only False entries;

“No”, otherwise.

Sanity Check (1/2)

$$\begin{bmatrix} T & F \\ F & T \end{bmatrix} = \begin{bmatrix} T & F \\ F & T \end{bmatrix} \times \begin{bmatrix} T & F \\ F & T \end{bmatrix}$$

\xrightarrow{n}
 $\uparrow n$

$$\begin{bmatrix} F & T \\ T & F \end{bmatrix} = \begin{bmatrix} T & F \\ F & T \end{bmatrix} \times \begin{bmatrix} F & T \\ T & F \end{bmatrix}$$

$$\begin{bmatrix} F & T \\ T & F \end{bmatrix} = \begin{bmatrix} F & T \\ T & F \end{bmatrix} \times \begin{bmatrix} T & F \\ F & T \end{bmatrix}$$

$$\begin{bmatrix} T & F \\ F & T \end{bmatrix} = \begin{bmatrix} F & T \\ T & F \end{bmatrix} \times \begin{bmatrix} F & T \\ T & F \end{bmatrix}$$

Input:

(1) two n by n Boolean matrices A and B

(2) $S = \{P_2, P_3\}$ (given as symbols rather than the explicit matrices)

Output:

“No” because $P_2 \& P_3 = \begin{bmatrix} F & T \\ T & F \end{bmatrix}$.

Sanity Check (2/2)

$$\begin{bmatrix} T & F \\ F & T \end{bmatrix} = \begin{bmatrix} T & F \\ F & T \end{bmatrix} \times \begin{bmatrix} T & F \\ F & T \end{bmatrix}$$

\xleftrightarrow{n}
 $\uparrow n$

$$\begin{bmatrix} F & T \\ T & F \end{bmatrix} = \begin{bmatrix} T & F \\ F & T \end{bmatrix} \times \begin{bmatrix} F & T \\ T & F \end{bmatrix}$$

$$\begin{bmatrix} F & T \\ T & F \end{bmatrix} = \begin{bmatrix} F & T \\ T & F \end{bmatrix} \times \begin{bmatrix} T & F \\ F & T \end{bmatrix}$$

$$\begin{bmatrix} T & F \\ F & T \end{bmatrix} = \begin{bmatrix} F & T \\ T & F \end{bmatrix} \times \begin{bmatrix} F & T \\ T & F \end{bmatrix}$$

Input:

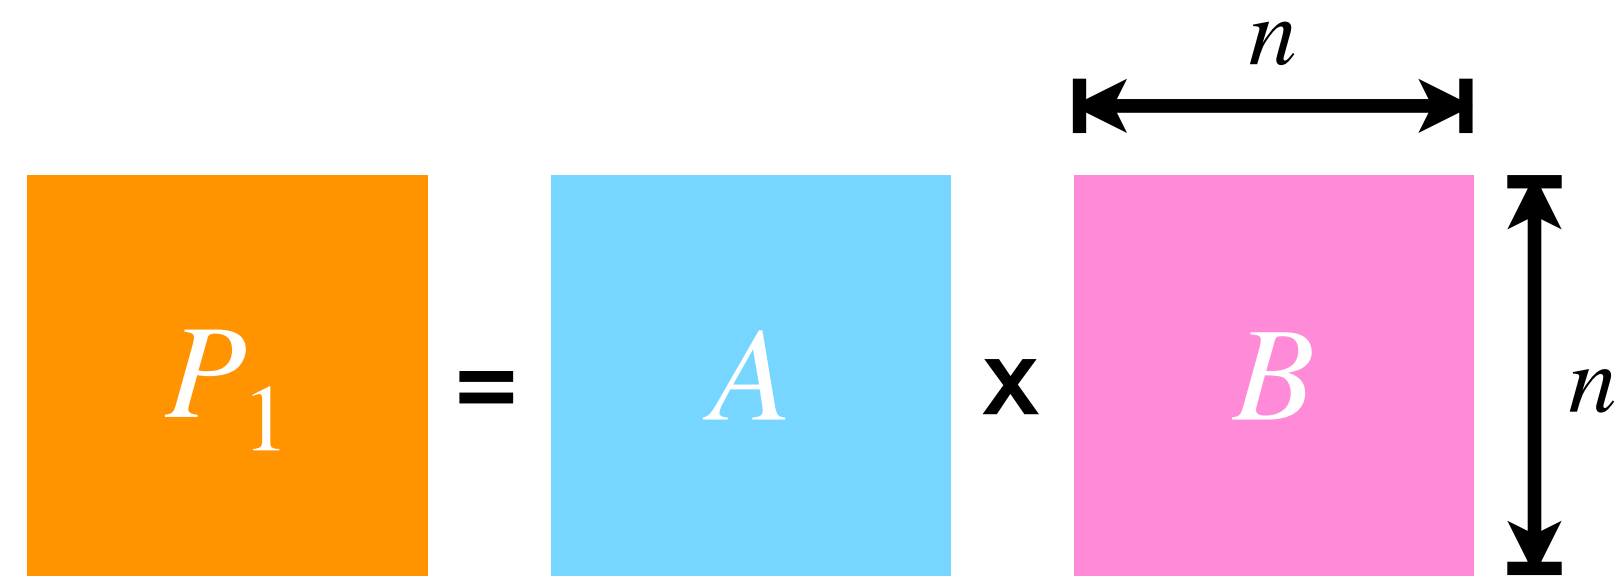

(1) two n by n Boolean matrices A and B

(2) $S = \{P_1, P_2, P_4\}$ (given as symbols rather than the explicit matrices)

Output:

“Yes” because $P_1 \& P_2 \& P_4 = \begin{bmatrix} F & F \\ F & F \end{bmatrix}$.

Main Message

$$P_1 = A \times B$$

$$P_2 = A \times \bar{B}$$

$$P_3 = \bar{A} \times B$$

$$P_4 = \bar{A} \times \bar{B}$$

Input:

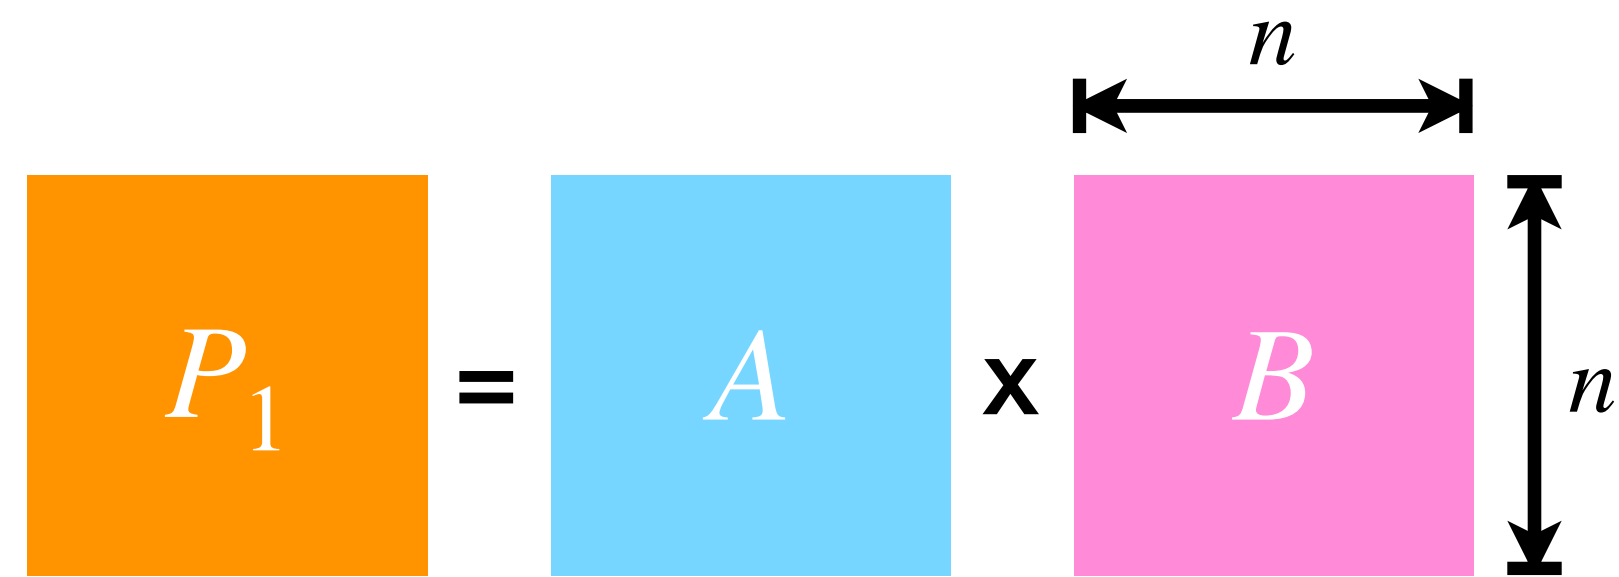

(1) two n by n Boolean matrices A and B

(2) a non-empty subset S of $\{P_1, P_2, P_3, P_4\}$ (given as symbols rather than the explicit matrices)

Our Main Theorem.

Verifying whether the product of GBMM contains only False entries can be done in deterministic $O(n^2)$ time.

Is Our Result Interesting? (1/3)

$$P_1 = A \times B$$

$$P_2 = A \times \bar{B}$$

$$P_3 = \bar{A} \times B$$

$$P_4 = \bar{A} \times \bar{B}$$

Our Main Theorem.

Verifying whether the product of GBMM contains only False entries can be done in **deterministic $O(n^2)$ time.**

By a reduction from Diameter 2 or 3
[Aingworth, Chekuri, Indyk, and Motwani'99]

Verifying whether the product of GBMM contains only True entries needs **$O(n^3)$ time by any known combinatorial algorithm.**

Is Our Result Interesting? (2/3)

$$P_1 = A \times B$$

$$P_2 = A \times \bar{B}$$

$$P_3 = \bar{A} \times B$$

$$P_4 = \bar{A} \times \bar{B}$$

Our Main Theorem.

Verifying whether the product of GBMM contains only False entries can be done in **deterministic $O(n^2)$ time.**

By Freivalds' algorithm [Freivalds'77] (noting that it has no known **efficient** deterministic alternative)

Verifying whether the product of GBMM contains only False entries can be done in **randomized $O(n^2)$ time.**

Is Our Result Interesting? (3/3)

$$P_1 = A \times B$$

$$P_2 = A \times \bar{B}$$

$$P_3 = \bar{A} \times B$$

$$P_4 = \bar{A} \times \bar{B}$$

Our Main Theorem.

Verifying whether the product of GBMM contains only False entries can be done in **deterministic $O(n^2)$ time.**

Our main result can be applied to detect the existence of several small subgraphs.

To be introduced in a minute.

Application I

Detecting Designated Colored 4-Cycles

Problem Definition

Fix an edge-colored 4-cycle C .

Input: an edge-colored complete graph G .

Output:

“Yes”, G contains C as a subgraph;

“No”, otherwise.

Problem Definition

General (monochromatic) graphs can be thought as 2-edge-colored complete graphs.

Fix an edge-colored 4-cycle C .

Input: an edge-colored complete graph G .

Output:

“Yes”, G contains C as a subgraph;

“No”, otherwise.

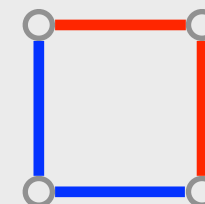

Detecting Different Designated 4-Cycles Can Have Different Complexities, Unconditionally

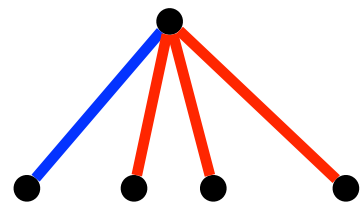

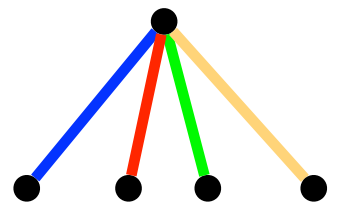

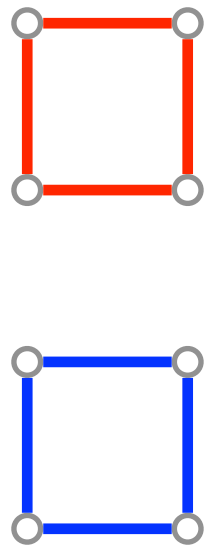

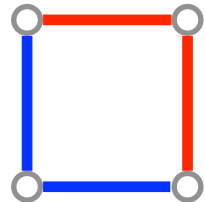

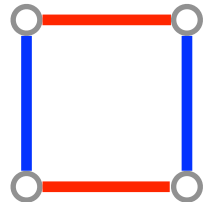

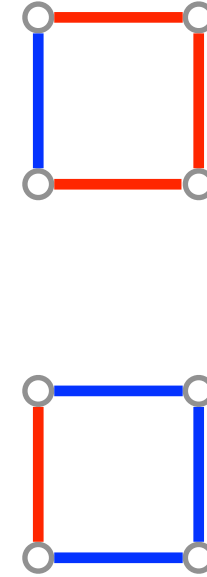

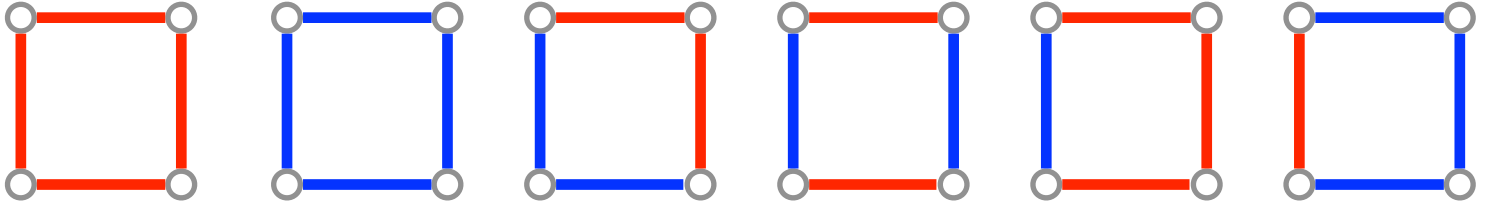

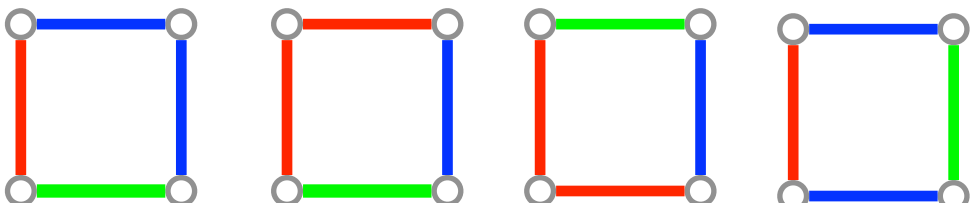

Fix an edge-colored 4-cycle C .

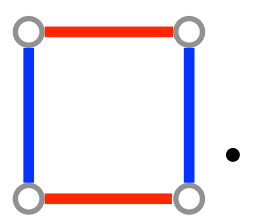

Input: an edge-colored complete graph G .

Case I: fix $C =$ . Any single-pass streaming algorithm that detects C requires $\Omega(n^2)$ space.

Case II: fix $C =$ . There is a single-pass streaming algorithm that detects C using $O(n)$ space.

	The number of colors of edges incident to each vertex is at most 2.					at most 3.	
	The number of edge colors in G is at most 2.				The number of edge colors in G can be more than 2.

Application II

Detecting Designated Four-Node Induced Subgraphs

Problem Definition

Fix a 4-node graph H .

Input: a triangle-free undirected simple graph G .

Output:

“Yes”, G contains H as an induced subgraph;

“No”, otherwise.

Problem Definition

For each H , with one exception that $H = P_4$, the known best algorithm that solves our problem for general G needs triangle time. [WWWY'15]

Fix a 4-node graph H .

Input: a triangle-free undirected simple graph G .

Output:

“Yes”, G contains H as an induced subgraph;

“No”, otherwise.

Our Result

Fix a 4-node graph H .

Input: a triangle-free undirected simple graph G .

For each H , detecting H for triangle-free graphs can be done in randomized $O(n^2)$ time.

Our Algorithm for a Simple Case: $H = P_4$

Fix $H = P_4$.

Input: a triangle-free undirected simple graph G .

Step 1. Use the color-coding technique to obtain a bipartite subgraph.

Our Algorithm for a Simple Case: $H = P_4$

Fix $H = P_4$.

Input: a triangle-free undirected simple graph G .

Step 1. Use the color-coding technique to obtain a bipartite subgraph.

Step 2. Compute an adjacency matrix A with rows corresponding to one part and columns corresponding to the other. Let $B = A^T$.

A	4	5	6
1	T	T	T
2	T	T	T
3	F	T	T

Our Algorithm for a Simple Case: $H = P_4$

A	4	5	6
1	T	T	T
2	T	T	T
3	F	T	T

Fix $H = P_4$.

Input: a triangle-free undirected simple graph G .

Step 1. Use the color-coding technique to obtain a bipartite subgraph.

Step 2. Compute an adjacency matrix A with rows corresponding to one part and columns corresponding to the other. Let $B = A^T$.

Step 3. Solve GBMM for $A\bar{B}$ & AB .

Our Algorithm for a Simple Case: $H = P_4$

Fix $H = P_4$.

Input: a triangle-free undirected simple graph G .

Deciding whether a general graph contains P_4 as an induced subgraph is equivalent to **recognizing cographs**.

The implementation of the recognition algorithm is complicated. The simplest one [HP'05] still is lengthy.

Our algorithm is a very simple alternative for triangle-free graph G .

Algorithm 2: Computing a factorizing permutation of a cograph
Input: A graph $G = (V, E)$ and an empty stack Q of vertices
Output: A permutation of V that is a factorizing permutation if G is a cograph
begin
 $\mathcal{P} = [V]$
 1 Choose an arbitrary vertex x of G as *Origin*
 if *Origin* is an isolated vertex or a universal vertex then
 2 | recurse on $G[V \setminus \{Origin\}]$
 while there exist some non-singleton parts do
 3 | if \mathcal{C}_{Origin} is not a singleton then
 | Use rule ?? on \mathcal{C}_{Origin} with *Origin* as pivot
 | Set $\bar{N}(Origin) \cap \mathcal{C}_{Origin}$ and $N(Origin) \cap \mathcal{C}_{Origin}$ as unused parts
 while there exist unused parts do
 | Pick an arbitrary unused part \mathcal{C} and an arbitrary vertex $y \in \mathcal{C}$
 | Set y as the pivot of \mathcal{C}
 | Refine the parts $\mathcal{C}' \neq \mathcal{C}$ of \mathcal{C} with rule ?? using the pivot set $N(y)$
 | Mark \mathcal{C} as used and the new created subparts without pivot as unused
 Let z_l and z_r be the pivots of the nearest non singleton parts to *Origin*
 respectively on its left and on its right
 4 | if z_l is adjacent to z_r , then *Origin* $\leftarrow z_l$ else *Origin* $\leftarrow z_r$
return \mathcal{P}
end

Algorithm 5: Recognition test
Input: Let $\sigma = x_1, \dots, x_n$ be a permutation of the vertex set of a graph G , σ is represented as a doubly linked list.
Output: σ a list of vertices
begin
 Let x_0 and x_{n+1} be added to σ (these vertices are dummies which are not twins with any other vertex)
 Let z be the current vertex, initially $z \leftarrow x_1$
 Let $succ(z)$ (resp. $prec(z)$) be the vertex following (resp. preceding z) in σ
 while $z \neq x_{n+1}$ do
 | if z and $prec(z)$ are twins (true or false) in $G(\sigma)$ then
 | | remove $prec(z)$ from σ
 | else
 | | if z and $succ(z)$ are twins (true or false) in $G(\sigma)$ then
 | | | $z \leftarrow succ(z)$
 | | | remove $prec(z)$ from σ
 | | else $z \leftarrow succ(z)$
 if $|\sigma - \{x_0, x_{n+1}\}| = 1$ then **return** G is a cograph else **return** $G(\sigma)$ contains a P_4
end

Our Algorithm for the Most Complicated Case: $H = 2K_2$

Fix $H = 2K_2$.

Input: a triangle-free undirected simple graph G .

We need a reduction to 3 different instances of GBMM.

Details are omitted in this talk.

Sketch of Our Deterministic Algorithms

For $S = \{P_1, P_2, P_3\}$

Step 1. Given the input matrices A and B , define an **implication graph** G_I as a sequence of **incremental edge updates**.

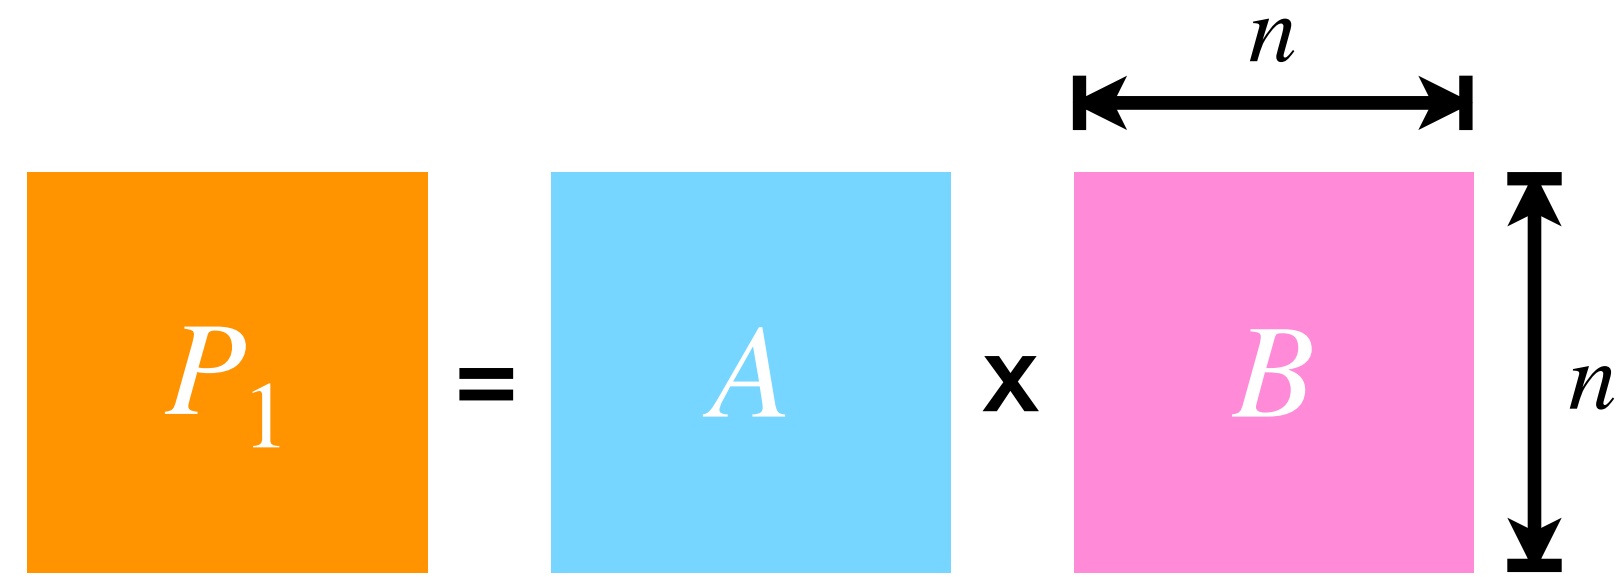

Step 2. Constructing G_I needs $O(n^3)$ time by the known best combinatorial algorithm [ACIM'99]. We show, however, that **identifying all components** in G_I after each incremental update can be done in $O(n^2)$ time.

Step 3. We use the information of the components in the **dynamic** G_I to avoid re-computing the same procedure incurred during the computation of P_1 & P_2 & P_3 . Our algorithm runs in deterministic $O(n^2)$ time.

For other S , GBMM can be solved by a simplified variant of our above algorithm.

Recap

Thank you! Any questions?

$$P_1 = A \times B$$

$$P_2 = A \times \bar{B}$$

$$P_3 = \bar{A} \times B$$

$$P_4 = \bar{A} \times \bar{B}$$

Input:

(1) two n by n Boolean matrices A and B

(2) a non-empty subset S of $\{P_1, P_2, P_3, P_4\}$ (given as symbols rather than the explicit matrices)

Our Main Theorem.

Verifying whether the product of GBMM contain only False entries can be done in deterministic $O(n^2)$ time.
